TITLE:

The Mutation Effect of a Combined Action of Ethylenimine and Ultra-Violet Rays upon Actinomycetes (Mutagennyy effekt kombinirovannogo deystviya etilenimina i ultrafioletovykh luchey na aktinomitsety)

PERIODICAL:

Doklady Akademii Nauk SSSR, 1957, Vol. 115, Nr 5, pp. 1015 - 1017  
(USSR)

ABSTRACT:

Swanson proved in 1948 that the frequency of mutation of Aspergillus terreus and Neurospora crassa increases more intensively after the treatment of their spores with small doses of bis-B-chlorethylmethylamine, if they are subsequently exposed to violet rays, than by an exposure to ultra-violet rays solely. It was therefore presumed that the environmental factors can produce an effect upon the sensitiveness of the cell with respect to the radiated energy, viz. that the frequency of mutation is not only a function of the absorbed energy. This induced the authors to study the effect of the combined action of ethylenimine- and ultra-violet rays upon various actinomycetes. They used Strepto-

myces aureo faciens No 112 and Str. griseus LS-1 (Actinomyces globisporus streptomycini). Both ethylenimine and a series of its derivatives show an effective "zytotoxic" action. Part of the initial spore suspension of the first-mentioned kind of fungus was kept during 5 and 20 hours (respectively) in solutions of ethylenimine of various concentrations (1 : 5000 to 1 : 8000) and was subsequently exposed to rays. An other part of the suspension was first exposed to rays and subsequently treated with ethylenimine solution (as above). The test in respect to the produced effect upon the vitality are given in table 1. It may be seen from this that the decay of spores as a consequence of their exposure to rays, increases intensively, provided that they were subject to a previous treatment with ethylenimine - compared with their mortality in case of an inverse sequence of the said factors. The vitality of the spores also decrease 50 times by their exposure to rays solely, if their dose has been increased from 2000 to 10.000 erg/mm<sup>2</sup>. It falls 80 times, if the spores are first exposed to rays and subsequently treated with ethylenimine, - viz.

Card 2/4

The Mutation Effect of a Combined Action of Ethylenimine and Ultra-Violet Rays  
upon Actinomycetes

only four times, - and with an inverted sequence of the factors (concentration 1 : 5000). The results obtained with Str. griseus were similar (analogous). The test results in respect to the frequency of mutation of the latter fundus in case of a combined action, when ethylenimine was applied first, are given in table 2. This frequency rises rapidly in the case of the latter sequence of treatments. The same results were obtained with Str. aureo faciens. As to the mechanism of the rapid rise of the frequency of mutations which were induced by ultra-violet rays, it may be assumed that the sensitization of the cells against ultra-violet rays increases under the effect of ethylenimine. By this, the action of the ultra-violet rays upon the nucleus is intensified. It may also be presumed that these rays excite the molecule ethylenimine and by this abruptly increase its reactivity. There are 2 figures, 2 tables and 1 Slavic reference.

TITLE: On a Finding of Open- Pored Pollen Grains of Paleozoic Angiosperms (O nakhodke pyl'tsy paleozoyskikh pokrytosamen-nykh s otkrytymi porami)

PERIODICAL: Doklady Akademii Nauk SSSR, 1958, Vol. 118, Nr 5, pp. 1034-1035 (USSR)

ABSTRACT: The findings of such a pollen in the Lower Carbon of the Podmoskovnyy basin (reference 1) and in the western part of the Donetskiy basin (reference 2), which is similar to the recent pollen of Myriophyllum, alder (Alnus), and birch (Betula) shifts back considerably the time of the appearance of angiosperms. 4-, 3- cornered or oval shaped outlines represent a morphologic peculiarity of the mentioned pollen. According to reference 1 open-pored pollen (only germinated pollen is open-pored) have never been found in the Paleozoic era of the mentioned basins and the probability of discovering them is very small. This is possible only in the case of an investigation of considerable quantities of pollen of angiosperms.

Card 1/8

On a Finding of Open-Pored Pollen Grains of  
Paleozoic Angiosperms.

20-118-5-53/597

For this purpose a special method is necessary which has been elaborated by the author. Coal and coal containing rock in which paleozoic pollen of angiosperms occurs after maceration is centrifuged in the Tule-liquid (specific weight = 2,4). The obtained mixture of spores and pollen is then centrifuged in the same liquid with a specific weight of 1,79 20 - 25 minutes. Thus, 3 layers are obtained. The wanted pollen can be found in the upper layer. In the case of a magnification of 400 times: 6 open-pored pollen grains were found. 5 of them belong to the 4-pored (Tetraporina), and 1 grain belongs to the 3-pored pollen (Triporina) (figure 1). A short description of the pollen is given. The finding of this pollen indicates the germinating through the pores in the case of the paleozoic angiosperms which is known of some recent angiosperms (Alnus, Betula and others). Further investigations of such pollen may contribute to the correct solution of the secret of the origin and the evolution of recent plants.

Rotatsionnyye vakuum-nasosy i kompressory s zhidkostnym porshnem (Rotary Liquid-Piston Vacuum Pumps and Compressors) Moscow, Mashgiz, 1960. 250 p. Errata slip inserted. 5,000 copies printed.

Reviewer: P.G. Udyma, Engineer; Ed.: Ya. G. Alaverdov, Engineer; Tech. Ed.: V.D. El'kind; Managing Ed. for Literature on Chemical and Textile Machine Building: V.I. Rybakova, Engineer.

PURPOSE: This book is intended for engineering personnel engaged in the construction, manufacture, and operation of rotary liquid-piston vacuum pumps.

COVERAGE: Fundamentals of the theory, design, and construction of rotary liquid-piston vacuum pumps are described and experimental and theoretical analyses of these machines are given. Included is the design of a rotary compressor with a rotating liquid container. Apparatus and individual subassemblies of vacuum and compressor installation equipment and of checking-and-measuring instruments are also described. No personalities are mentioned. There are 62 references:

ABSTRACT:

Teteryukov, V.I., Candidate of Technical Sciences

The Gas Compression Process in a Rotary Vacuum Pump With a Liquid Piston

Khimicheskoye mashinostroeniye, 1959, Nr 5, pp. 16-20 (USSR)

For studying the gas compression process in a rotary vacuum pump with a liquid piston (sucker) it is necessary to determine the changes in the volume of the working cells. With radial blades, this volume can be determined independently of the cavity in which a cell is located (suction or compression cavity), by the formula  $V = fb$ , where  $b$  - the length of rotor  $f = (y^2 - r_2^2) \frac{\pi}{360}$  and  $f$  - area of cell cross-section. In a general case  $f = (y^2 - r_2^2) \frac{\pi}{360}$ , where  $y$  - a variable radius drawn from the center of the rotor to the inside surface of the liquid ring;  $r_2$  - radius of the rotor bushing,  $\beta$  - angle between two rotor blades. The value of  $y$  changes differently in the suction and compression cavity, consequently the change of the volume of sections in these cavities is different. Formulas taken from a previous paper of the author (Ref.1) are given for  $y$  in the suction and compression cavities and for the volume of a working cell in these cavities. In a real gas compression process losses of volume and

Card 1/ 5

82778

SOV/184-59-5-6/17

The Gas Compression Process in a Rotary Vacuum Pump With a Liquid Piston

energy are caused by the effect of the dead space, the overflow of gas through the face gaps of the rotor, the pressure loss in the intake opening and the loss of gas through leakage. A real indicator diagram cannot be taken with an indicator. For this reason pressures at different points of the working chambers of the pump were measured with U-shaped mercury gages. From these measurements the dependence of the volume on the pressure was found and real indicator diagrams were plotted for various operating conditions (93%, 60%, 40% and 13% vacuum) at  $r_2 = 53$  mm,  $b = 218$  mm and  $\beta = 15^\circ$ . At a 93% vacuum, the valve on the suction line was closed and the pump ran practically idle, pumping the rest of the air out of the suction cavity. The fluid ring fitted tightly to the rotor bushing in the upper part of the pump (practically no dead space). The graph in Figure 3a shows that the energy of the pump is spent mainly for compressing the air leaking out of the compression and delivery cells into the suction cells and for displacing the atmospheric air entering the delivery cells through the open delivery part. The high energy losses at a high vacuum are caused by the connection of the delivery cells of the pump with the atmosphere. The delivery cells work with an air volume which is

Card 2/5

82778

SOV/18<sup>4</sup>-59-5-6/17

The Gas Compression Process in a Rotary Vacuum Pump With a Liquid Piston

greater than that which must be removed from the suction cavity. Calculations show that 34% of energy are wasted on account of divergence of the compression process in a rotary vacuum pump from that in a piston compressor (gas overflow between chambers). The following characteristics were calculated for a 93% vacuum; mean indicated pressure 0.475 kg/cm<sup>2</sup>; pump efficiency by the volume of cells in the lower position 4.2 m<sup>3</sup>/min; indicated power 4.45 hp; mechanical efficiency 0.54; isothermal efficiency 0.20. At a 60% vacuum the valve in the suction line was partly open and at a rarefaction of about 450 mm Hg was produced in the suction pipe. The atmospheric air was sucked in, compressed to 1.03 atmospheres and pushed out through the delivery pipe and the water separator. The liquid ring in the upper part of the pump deviated from the rotor bushing thus a part of the compressed air remained in the rotor cells and was pumped over into the suction cavity (indicator diagram Figure 3b). In this case the divergence between the real and the isothermal process is much smaller than at a 93% vacuum, because the volume of air drawn into the suction cells increases at a lower vacuum and, consequently, a smaller volume of atmospheric air enters the compression and delivery cells. In this way better characteristics are

Card 3/5

82778

SOV/184-59-5-6/17

The Gas Compression Process in a Rotary Vacuum Pump With a Liquid Piston

obtained: mechanical efficiency 0.82; pump efficiency  $4.7 \text{ m}^3/\text{min}$ ; indicated power 5.72 hp; isothermal efficiency 0.59. At a 40% vacuum (indicator diagram 3c) the characteristics are: mechanical efficiency 0.862; pump efficiency  $5 \text{ m}^3/\text{min}$ ; indicated power 5.44 hp; isothermal efficiency 0.67. The conditions of a 13.2% vacuum (Figure 3d) are not typical for a vacuum pump, since it works in this case as an air-blower: pump efficiency  $5.18 \text{ m}^3/\text{min}$ ; mechanical efficiency 0.86; indicated power 4.72 hp; isothermal efficiency 0.67. A higher pump efficiency is explained by a smaller overflow of compressed gas on account of a lower pressure drop between adjacent cells. The graphs in Figure 4 show the changes in the energy consumption for compressing the air at different vacuum levels for actual and isothermal processes. With a lower vacuum the energy required for the air compression increases and the mechanical losses decrease.. A comparison of a calculated with a real indicator diagram (Figure 5) shows a nearly complete coincidence of compression lines. It means that for calculation of a vacuum pump the process of compression can be held as proceeding according to the conditional

AUTHORS: Teteryukov, V.I., Candidate of Technical Sciences; Voronkov,  
A.E., Engineer

TITLE: New drowned centrifugal pump for pumping-over nitric acid

PERIODICAL: Khimicheskoye mashinostroyeniye, no. 2, 1962, 5-6

TEXT: The authors describe the design and operation of a test model of the 4 BXА-18 (4VKhA-18) vertical, single-stage, drowned centrifugal pump for pumping-over 15 to 60-% nitric acid at temperatures of up to 50°C. The pump has a capacity of 60 m<sup>3</sup>/hour at a pressure of 20 m of water column, a 63-% efficiency, and a speed of 2,930 r.p.m. Its electric motor has a capacity of 9 kw. The pump can operate at a submersion depth of the impeller ranging from 2 m to zero. Industrial tests of the pump proved satisfactory; after working 4000 hrs with a delivery of 37.5 m<sup>3</sup>/hr and 5720 hrs with a delivery of 45 m<sup>3</sup>/hr, no mechanical breakdowns or noticeable traces of corrosion were observed, although one of the teflon bearings showed wear of ✓

TITLE: Automatic argon arc welding of aluminum alloys

SOURCE: Svarochnoye proizvodstvo, no. 7, 1966, 26-28

TOPIC TAGS: arc welding, automatic welding, weld evaluation / AMg61 aluminum alloy

ABSTRACT: The effect of various parameters (weld speed, arc voltage, etc.) on the quality of welded AMg61 aluminum alloy joints was studied with the aid of an ADPG-500 automatic arc welder. High speed (60-70 M/hr) single pass welding of 4-12 mm thick aluminum alloy provided high quality welds, doubled productivity, decreased argon consumption and welding deformation as compared with existing techniques. Weld strength was about 90% of the base metal strength. The electric circuit was changed in order to eliminate the fusion of the tip at the moment the arc is extinguished. Joint penetration "h" and reinforcement were increased by increasing welding current "I" according to the approximate relationship  $h = \alpha I$  where  $\alpha$  is a coefficient  $\approx 0.008$  mm/amp. The increase in the arc voltage had no considerable effect on the joint penetration; however, it affected the width of the weld. The optimal relationship between weld current and voltage is graphed. The weld speed affected the weld bead cross section area. In

ACC NR: AP6023440

a single pass weld, a 60-70 M/hr weld speed considerably decreased porosity. On the other hand, speeds of 28 M/hr produced bubbles up to 2 mm in diameter. Metal electrodes of 2 mm diameter provided a stable arc for current intensities of 70-130 amp/mm<sup>2</sup>. Optimal weld regimes are listed in a table for welds performed on metal sheets with dimensions of 150 x 400 mm. Weld quality was checked by radiographic and mechanical tests. AUTHOR: Teteryukov, V.I., Candidate of Technical Sciences

TITLE: Rotation-Type Vacuum Pumps With Liquid Piston (Rotatsionnyye vakuum-nasosy s zhidkostnym porshnem)

PERIODICAL: Khimicheskaya nauka i promyshlennost', 1958, Vol III, Nr 6, pp 790-797 (USSR)

ABSTRACT: Rotation-type vacuum pumps with liquid piston have no valves, are not sensitive to sand, slag, etc, do not need lubrication, but have only an efficiency factor of 35 - 40%. The operation conditions of these pumps have been investigated on the industrial type RMK-2 (Figure 1). The form of the liquid ring of these pumps plays an important role. The form of this ring at maximum vacuum is shown in Figures 2 and 3. The output of the pump is  $2.18 \text{ m}^3/\text{min}$ , whereas the volume covered by the rotor is  $5.83 \text{ m}^3/\text{min}$ . The efficiency factor is 0.375. The loss of efficiency is due to the flow of compressed air from the pressure zone to the suction zone. Every particle in the liquid ring of the vacuum pump is affected by the acceleration of the centrifugal force, by the acceleration of the mass of the liquid, by the gas pressure, etc. For the determination of the liquid speed in any cross section the thickness of the liquid ring in this section must be known (Figure 5). Under

Card 1/2

Rotation-Type Vacuum Pumps With Liquid Piston

SOV/63-3-6-13/43

the action of inertia forces the liquid moves to the outside of the rotor blades (Figure 6). The form of the liquid ring in the compression zone is calculated and drawn (Figure 7). The size and the position of the suction and especially the compression opening have a considerable influence on the operation condition of the pump. Investigations have shown that the optimum size of the compression opening depends on the value of the vacuum. It has been shown that the output of the pump may be increased from  $3.5 \text{ m}^3/\text{min}$  to  $3.66 \text{ m}^3/\text{min}$ , the isothermal efficiency factor from 41.5% to 42.7%, but the water consumption increases two times.

There are 2 photos, 7 diagrams and 3 graphs.

Extraction methods using an immobilized phase. I. Immobilization of the aqueous phase with regenerated cellulose. T. Károly Tettamanti and Andor Ujkert (Tech. Univ., Budapest) *Acta Litterarum Acad. Sci. Hung.* 16, 479-88 (1958) (in English). A method is described in which the formation of stable emulsions in liquid-liquid extns. is avoided in extns. of aq. solns. with org. solvents. The aq. solns. are absorbed in strips of cellulose sponge, which swell and retain 7 to 15 times their wt. of water. The extn. then may be conducted, e.g. in a Soxhlet extractor. The usual equations for liquid-liquid extns. apply, with a correction for the part of the org. phase,  $r$ , which is retained by the sponge and the immobilized aq. phase. Thus  $K_L$ , the virtual partition coeff., =  $K(1 - r)/(1 + rK)$ , and  $K = f_k$ .  $K$  is the extn. coeff.,  $f$  is the vol. ratio of the mobile to the immobilized phase, and  $k$ , the distribution coeff. = (concen. in mobile phase)/(concen. in immobilized phase).  $K_L$  may be detd. experimentally by the relation  $K_L = (Y_m/Y_{(m+1)}) - 1$ , where  $Y_m$  is the yield of the  $m^{\text{th}}$  extn. *Patricia H. Moyle*

TITLE: Trucks for combined operating modes [Trucks equipped to operate from rails or unpaved roads]

SOURCE: Tyl i snabzheniye sovetskikh voorushennykh sil, no. 12, 1966, 85-87

TOPIC TAGS: special purpose truck, motor vehicle, railway construction, railway transportation, railway engineering

ABSTRACT: This article states that for the fast restoration of rail service, railway construction and maintenance troops are supplied with modern equipment, such as trucks and truck-cranes capable of operating on unpaved roads and on rails. Specially designed equipment makes it possible to quickly adapt motor vehicles for operation on railroads of any gauge. The K-162, K-104, and K-52 truck-cranes

Surface layering in binary liquid systems. B. Ya. Tietelbaum. Russ. J. Phys. Chem. 37, 149-152 (1963). Measurements of the surface tension  $\sigma$  (by the method of max. pressure of bubble formation, accurate to within 0.1 erg/cm<sup>2</sup>, cm.) of mixts. of methylene with MeOH (mole fraction  $N_1$ ) at different temp.,  $t$ , are represented in the form of a space model in the coordinates  $N_1$ ,  $t$ . Only the polytherm corresponding to  $N_1 = 0.0$  is rectilinear over the whole temp. range (0-40°), all other polytherms show a deviation from linearity at some  $t$ , the temp. coeff.  $\gamma = \partial\sigma/\partial t$  decreasing with falling temp., and even becoming neg. ( $\gamma > 0$ ) for certain compns. These deviations from linearity are interpreted as sepn. into 2 liquid layers at the surface. The projection of the corresponding points on the  $N_1$ ,  $t$  plane gives a surface miscibility curve similar to but not identical with the bulk miscibility curve that indicates the existence of a temp.

range in which the liquids are layered at the surface while still homogeneous in the bulk. This surface layering (presence, at the surface, of a surface structure of 3 condensate nuclei) at high concns. of miscibility may give rise to the formation of a 2-dimensional cellular structure, producing particularly high surface viscosity. At high MeOH, the equilibrium is apparently unstable and undergoes decompr., with the dispersed phase going over into the bulk soln. and the surface becoming wholly covered with the MeOH-rich soln. The form of polytherm characteristic of liquid systems susceptible of surface layering appears to consist of 2 rectilinear branches; the higher-temp. portion corresponds to the initial surface soln., whereas the lower-temp. branch, lying below (i.e. at lower  $\sigma$ ) the prolongation of the 1st portion, corresponds to the soln. produced by the layering. The intermediate portion may, but need not, have a range of neg.  $\gamma$ . In systems with a lower crit. temp. of soln., surface layering can be expected to occur at a lower temp. than in the bulk.
